

## Experiment-2

### Cryptanalysis of RSA

Date: 31/7/25

#### AIM

Implementation of Cryptanalysis using RSA.

#### PROCEDURE

Step-1: Install VMWare and host Kali Linux.

Step-2: Login to Kali Linux and open Terminal and run commands.

Step-3: Use Hexadecimal to decimal convertor.

Step-4: Use factordb.com to find the factors for the decimal value.

Step-5: Write an exploit in python and get the plain text.

#### SOURCECODE

```
$ mkdir rsa  
$ cd rsa  
$ ls  
$ cat enc.txt  
$ cat Pubkey.pem  
→ To generate Public Key  
$ openssl rsa -pubin -inform PEM -text -noout < Pubkey.pem
```

- Copy the hexadecimal Code into a notepad.
  - As it is a hexadecimal we can convert it into decimal for gaining the Plain-text.
  - Hexadecimal to decimal Converter.
  - Click on Convert and Convert the hexadecimal to decimal.
  - Now Copy the decimal value and Paste in the notepad as n value.
  - We need to factorize n.
  - So go to website factordb.com click Search, Paste decimal value of n and click on factorize. We get the value.
  - Create a exploit.py
  - To install PyCrypto  
PiP install PyCryptodome
  - Copy the Code in the exploit.py file and Paste it
- $n = 188198812920679638697239461650439807$   
 $1635633794173827007633564229888594152$   
 $e = 65537$ .
- $P = 39807508642406493739712550550864911990$   
 $6436234252670840685189575946388957261$   
 $q = 472972148107435302530253622367197304822$   
 $4632914695302971146459852171130520711$ .

$$\phi_{-n} = (p-1) * (q-1)$$

$d = \text{inverse}(e, \phi_{-n})$

Key = RSA::Construct((n, e, d, p, q))

fn = "Private.Pem"

with open(fn, "wb") as f:

f.write(key.exportKey())

,

→ Python exploit.py

→ To decrypt the text

openssl pkcs8utl -decrypt -in enc.txt -out  
dec.txt -inkey Private.Pem.

→ \$ cat dec.txt

RSA IS EASY.

2/1

OUTPUT

RSA is easy .

$$(1-1) + (1-1) = 0$$

(a - b)  $\neq$  (b - a)

((a - b) \* c)  $\neq$  a \* c - b \* c

"meli - tafni" =

t col("row", "row")

((yeniFirstIndex + 1) \* 10) + t
